

Normalization

1 2 3 Normal Forms

Schema Refinement

- Redundancy
- Schema Refinement
 - Minimizing Redundancy
 - Functional Dependencies (FDs)
 - Normalization using FDs
 - First Normal Form (1NF)
 - Second Normal Form (2NF)
 - Third Normal Form (3NF)
 - Boyce-Codd Normal Form (BCNF)
 - Multivalued Dependencies (MVDs), Join Dependencies JDS
 - Normalization using MVDs and JDs
 - Higher Normal Forms (4NF, 5NF)

Normal Forms

First Normal Form

- Domain is **atomic** if its elements are considered to be indivisible units
 - Examples of non-atomic domains:
 - Set of names, composite attributes
 - Identification numbers like CS101 that can be broken up into parts
- A relational schema R is in **first normal form** if the domains of all attributes of R are atomic
- Non-atomic values complicate storage and encourage redundant (repeated) storage of data
 - Example: Set of accounts stored with each customer, and set of owners stored with each account
 - We assume all relations are in first normal form (and revisit this in Chapter 22: Object Based Databases)

First Normal Form (Cont.)

- Atomicity is actually a property of how the elements of the domain are used.
 - Example: Strings would normally be considered indivisible
 - Suppose that students are given roll numbers which are strings of the form CS0012 or EE1127
 - If the first two characters are extracted to find the department, the domain of roll numbers is not atomic.
 - Doing so is a bad idea: leads to encoding of information in application program rather than in the database.

1NF Summarized

- Each attribute must be atomic (single value)
 - No repeating columns within a row (composite attributes)
 - No multi-valued columns.
- All key attributes defined
- All attributes dependent on primary key
- 1NF simplifies attributes
 - Queries become easier.

Dependencies and Normal Form

- The schema R is in 1NF if domain of all attributes of R is atomic
- Desirable
 - PK dependencies
- Undesirable
 - Partial Key : based on part of composite PK
 - Transitive: one nonprime attribute depends on another nonprime attribute

Normal Forms

- Scalar Values
 - 1 NF
- Normal Forms based on PK
 - 2 NF
 - 3 NF
- Normal Forms based on CKs
 - Boyce-Codd Normal Form (BCNF)
- Other Normal Forms
 - 4 NF (Multivalued Dependencies)
 - 5 NF (Join Dependencies)
 - Deal with very rare practical situations

Normal Forms

- 1NF : A relation is in a first normal form, if every tuple contains exactly one value for each attribute
- Example: **Suppliers1** (S#, p#, status, city, qty)
- Primary key (S#, P#)
- City → status (FD)
- FD Diagram (FDD) can be drawn
- Observe
 - Status depends on the city (FD)
 - City depends only on the supplier number
- Primary Key: (s#,p#) -> qty
- Partial: s#-> city
- Transitive: S#->city, city->status implies s#-> status

Redundancies in Suppliers1

Suppliers1 (s# , p#, status, city, qty)

- **Insert:** We cannot insert the fact that a particular supplier is located in the city unless he/she actually supplies some part
- The Suppliers1 may not show a supplier is located in Chennai
- **Delete:** If we delete a sole Suppliers1 tuple for a particular supplier, we also delete that he/she is located in a particular city
- **Update:** to update the city for a particular supplier

Schema Refinement for Suppliers1

- Refined Schema Suppliers1
 - Suppliers2 (S#, status, city)
 - Primary : $s\# \rightarrow$ city
 - Transitive: $s\# \rightarrow$ city, city- \rightarrow status implies $s\# \rightarrow$ status
 - Suppliers_Parts (S#, P#, qty)
 - Primary: $(s\#, p\#) \rightarrow$ qty
- Insert: We can insert the info that s-5 is located in Pune although s-5 does not currently supply any part
- Delete: We do not lose the info that s-18 is located in Surat even if all the s-18 tuples from the suppliers_parts are deleted
- Update: city for a supplier can be updated easily through suppliers2

Second Normal Form 2NF

- A relation is in 2NF only if it is in 1NF and every nonkey attribute is irreducibly dependent on the primary key.
(here, we are assuming only single candidate (hence primary) key case)
- The original relation ***Suppliers1*** can be converted to the 2NF form by taking projection of it to a set of 2 relations ***suppliers2*** and ***suppliers_parts***
- All relations with single attribute PK are in 2 NF!!
- 2NF applies to relations with composite keys

2 NF

- A relation that is in 1NF & every non-PK attribute is fully dependent on the PK, is said to be in 2 NF

2NF Problems: Suppliers2

Suppliers2 (S#, status, city)

- Primary : $s\# \rightarrow \text{city}$
- Transitive: $s\# \rightarrow \text{city}$, $\text{city} \rightarrow \text{status}$ implies $s\# \rightarrow \text{status}$
- Insert: we cannot insert the fact that a particular city has a particular status unless we have some supplier located in that city
- Delete: if we delete a sole tuple for a particular city we delete the information for the supplier and also the information that a city has a particular status
- Update: the status for a city appears many a times in the suppliers2. The change in the Mumbai status from 80 to 90 may need changes in 100 tuples

Schema Refinement for Suppliers2

- Replace **Suppliers2 (s#,city, status)** by
 - **Suppliers3 (S#, city)**
 - **City_Info (city, status)**
- **3NF** : A relation is in a 3NF if it is in 2NF and every nonkey attribute is not transitively dependent on the primary key
- A relation is in a 3NF if nonkey attributes are:
 - Mutually independent
 - Irreducibly/nontransitively dependent on the primary key
- A nonkey attribute is any attribute that does not participate in the primary key of that relation

3 NF

- A relation that is in 1NF & 2 NF & no non-PK attribute is transitively dependent on the PK, is said to be in 3 NF

Heath's Theorem

- $R(A,B,C)$ where A B C are sets of attributes
- If R has FD $A \rightarrow B$, then R equals join of $\{A B\}$ and $\{A C\}$

- Example:

S (s#, status, city) ;

PK: $s\#$ implies $s\# \rightarrow \text{city}$ and $s\# \rightarrow \text{status}$

FD: $\text{City} \rightarrow \text{status}$ is troublesome (out of non-candidate key)

Then decomposition

($s\#, \text{city}$), (status, city) is **Dependency Preserving**

Heath's Theorem

- it says that a relation R over an attribute set U and satisfying a functional dependency $X \rightarrow Y$ can be safely split in two relations having the lossless-join decomposition property, namely into

$$\pi_{XY}(R) \bowtie \pi_{XZ}(R) = R$$

- where $Z = U - XY$ are the rest of the attributes.
- functional dependency provides a simple way to construct a lossless-join decomposition of R in two smaller relations

Normal Forms

- Returning to the issue of schema refinement, the first question to be asked is whether any refinement is needed!
- If a relation is in a certain *normal form* (BCNF, 3NF etc.), it is known that certain kinds of problems are avoided/minimized. This can be used to help us decide whether decomposing the relation will help.
- Role of FDs in detecting redundancy:
 - Consider a relation R with 3 attributes, ABC.
 - No FDs hold: There is no redundancy here.
 - Given $A \rightarrow B$: Several tuples could have the same A value, and if so, they'll all have the same B value!

Boyce-Codd Normal Form BCNF (1974)

- 2 or more candidate keys
 - Composite candidate keys
 - Overlapped keys
-
- A relation is in BCNF if and only if only determinants are candidate keys

BCNF

- Based on FDs that take into account all candidate keys of a relation
- For a relation with only 1 CK (PK), 3NF & BCNF are equivalent
- A relation is said to be in BCNF if every determinant is a CK

BCNF

- Relation **Suppliers1** (**s#, status, city, p#, qty**) is not in BCNF. It has 3 determinants **s#, city** and **(s#,p#)**
- Primary Key: **(s#,p#) -> qty**
- Partial: **s#-> city**
- Transitive: **S#->city, city->status implies s#-> status**
- Relation **Suppliers2(s#, status, city)** is not in BCNF. It has **s#** and **city** as determinants where **city** is nonPK attribute
- But **SP (s#,p#,qty)**, **SC (s# ,city)** and **CS (city,status)** are in BCNF

Nonoverlapping candidate keys

$S(\underline{s\#}, \underline{sname}, city, status)$

- $s\#$ and $sname$ are candidate keys and $city \rightarrow status$ no longer holds CK:
 - $s\# \rightarrow sname, city, status$
 - $sname \rightarrow s\#, city, status$
 - $s\# \leftrightarrow sname$
 - S is in BCNF

Overlapping candidate keys

SSP(s#, sname, p#, qty) is not in BCNF

CK:

- $(s\#, p\#) \rightarrow \text{qty}$
 - $(sname, p\#) \rightarrow \text{qty}$
 - $s\# \leftrightarrow sname$
-

- Redudndancies: same (supplier number, name) pair repeated for various parts that the supplier is supplying
- SS(s#, sname) , SP(s#,p#,qty)

Boyce-Codd Normal Form

- A relation schema R is in BCNF with respect to a set F of functional dependencies if for all functional dependencies in F^+ of the form

$$\alpha \rightarrow \beta$$

where $\alpha \subseteq R$ and $\beta \subseteq R$, at least one of the following holds:

- $\alpha \rightarrow \beta$ is trivial (i.e., $\beta \subseteq \alpha$)
- α is a superkey for R

Boyce-Codd Normal Form (Cont.)

- Example schema that is **not** in BCNF:

in_dep (ID, name, salary, dept_name, building, budget)

because :

- $\text{dept_name} \rightarrow \text{building}, \text{budget}$
 - holds on *in_dep*
 - but*
 - *dept_name* is not a superkey
- When decompose *in_dept* into *instructor* and *department*
 - *instructor* is in BCNF
 - *department* is in BCNF

Decomposing a Schema into BCNF

- Let R be a schema R that is not in BCNF. Let $\alpha \rightarrow \beta$ (nontrivial where α is not a superkey) be the FD that causes a violation of BCNF.
- We decompose R into:
 - $(\alpha \cup \beta)$
 - $(R - (\beta - \alpha))$
- In our example of in_dep ,
 - $\alpha = dept_name$
 - $\beta = building, budget$and in_dep is replaced by
 - $(\alpha \cup \beta) = (\underline{dept_name}, building, budget)$
 - $(R - (\beta - \alpha)) = (\underline{ID}, name, dept_name, salary)$

Example

- $R = (A, B, C)$
 $F = \{A \rightarrow B, B \rightarrow C\}$
- $R_1 = (A, B), R_2 = (B, C)$
 - Lossless-join decomposition:

$$R_1 \cap R_2 = \{B\} \text{ and } B \rightarrow BC$$

- Dependency preserving
- $R_1 = (A, B), R_2 = (A, C)$
 - Lossless-join decomposition:

$$R_1 \cap R_2 = \{A\} \text{ and } A \rightarrow AB$$

- Not dependency preserving
(cannot check $B \rightarrow C$ without computing $R_1 \bowtie R_2$)

BCNF and Dependency Preservation

- database consistency constraints: primary-key constraints, functional dependencies, check constraints, assertions, and triggers.
- It is not always possible to achieve both BCNF and dependency preservation
- Consider a schema:
 $\text{dept_advisor}(s_ID, i_ID, \text{department_name})$
- With function dependencies:
 $i_ID \rightarrow \text{dept_name}$
 $s_ID, \text{dept_name} \rightarrow i_ID$
- dept_advisor is not in BCNF
 - i_ID is not a superkey.
- Any decomposition of dept_advisor will not include all the attributes in
 $s_ID, \text{dept_name} \rightarrow i_ID$
- Thus, the composition is NOT be dependency preserving

Dependency Preservation

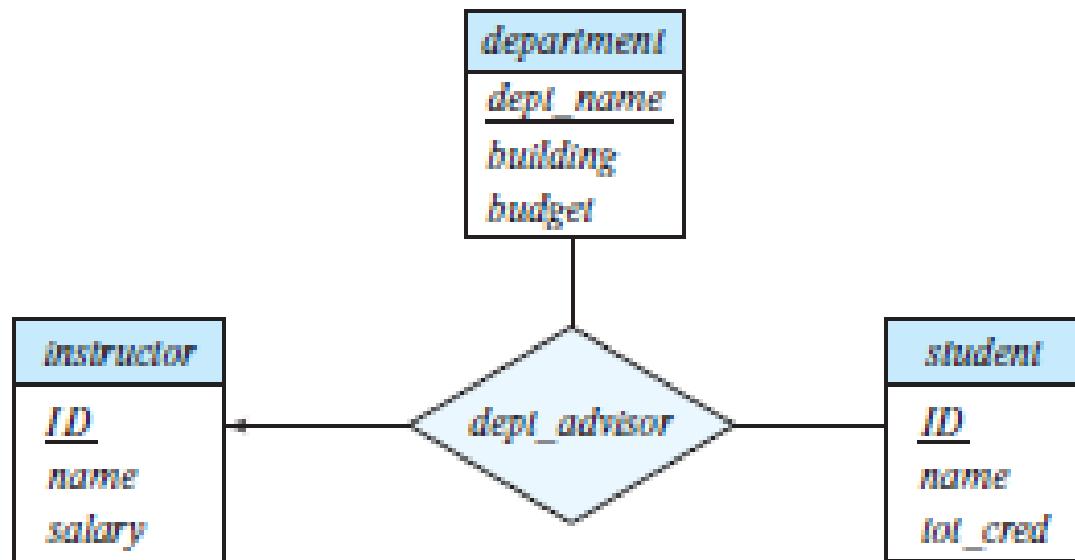

Figure 7.6 The *dept_advisor* relationship set.

Third Normal Form

- A relation schema R is in **third normal form (3NF)** if for all:

$$\alpha \rightarrow \beta \text{ in } F^+$$

at least one of the following holds:

- $\alpha \rightarrow \beta$ is trivial (i.e., $\beta \in \alpha$)
 - α is a superkey for R
 - Each attribute A in $\beta - \alpha$ is contained in a candidate key for R .
(NOTE: each attribute may be in a different candidate key)
- If a relation is in BCNF it is in 3NF (since in BCNF one of the first two conditions above must hold).
 - Third condition is a minimal relaxation of BCNF to ensure dependency preservation (will see why later).

3NF Example

- Consider a schema:
 $\text{dept_advisor}(s_ID, i_ID, \text{dept_name})$
- With function dependencies:
 $i_ID \rightarrow \text{dept_name}$
 $s_ID, \text{dept_name} \rightarrow i_ID$
- Two candidate keys = $\{s_ID, \text{dept_name}\}, \{s_ID, i_ID\}$
- We have seen before that dept_advisor is **not** in BCNF
- R , however, is in 3NF
 - $s_ID, \text{dept_name}$ is a superkey
 - $i_ID \rightarrow \text{dept_name}$ and i_ID is NOT a superkey, but:
 - $\{\text{dept_name}\} - \{i_ID\} = \{\text{dept_name}\}$ and
 - dept_name is contained in a candidate key

Redundancy in 3NF

- Consider the schema R below, which is in 3NF

- $R = (J, K, L)$
- $F = \{JK \rightarrow L, L \rightarrow K\}$
- And an instance table:

J	L	K
j_1	l_1	k_1
j_2	l_1	k_1
j_3	l_1	k_1
null	l_2	k_2

- What is wrong with the table?
 - Repetition of information
 - Need to use null values (e.g., to represent the relationship l_2, k_2 where there is no corresponding value for J)

Comparison of BCNF and 3NF

- Advantages to 3NF over BCNF. It is always possible to obtain a 3NF design without sacrificing losslessness or dependency preservation.
- Disadvantages to 3NF.
 - We may have to use null values to represent some of the possible meaningful relationships among data items.
 - There is the problem of repetition of information.

Goals of Normalization

- Let R be a relation scheme with a set F of functional dependencies.
- Decide whether a relation scheme R is in “good” form.
- In the case that a relation scheme R is not in “good” form, need to decompose it into a set of relation scheme $\{R_1, R_2, \dots, R_n\}$ such that:
 - Each relation scheme is in good form
 - The decomposition is a lossless decomposition
 - Preferably, the decomposition should be dependency preserving.

How good is BCNF?

- There are database schemas in BCNF that do not seem to be sufficiently normalized
- Consider a relation
 - *inst_info (ID, child_name, phone)*
 - where an instructor may have more than one phone and can have multiple children
 - Instance of *inst_info*

<i>ID</i>	<i>child_name</i>	<i>phone</i>
99999	David	512-555-1234
99999	David	512-555-4321
99999	William	512-555-1234
99999	William	512-555-4321

How good is BCNF? (Cont.)

- There are no non-trivial functional dependencies and therefore the relation is in BCNF
- Insertion anomalies – i.e., if we add a phone 981-992-3443 to 99999, we need to add two tuples
 - (99999, David, 981-992-3443)
 - (99999, William, 981-992-3443)

Higher Normal Forms

- It is better to decompose *inst_info* into:
 - *inst_child*:

<i>ID</i>	<i>child_name</i>
99999	David
99999	William

- *inst_phone*:

<i>ID</i>	<i>phone</i>
99999	512-555-1234
99999	512-555-4321

- This suggests other normal forms, such as Fourth Normal Form (4NF), which we shall see later

Functional Dependency Theory

Functional-Dependency Theory Roadmap

- We now consider the formal theory that tells us which functional dependencies are implied logically by a given set of functional dependencies.
- We then develop algorithms to generate lossless decompositions into BCNF and 3NF
- We then develop algorithms to test if a decomposition is dependency-preserving

Closure of a Set of Functional Dependencies

- Given a set F of functional dependencies, there are certain other functional dependencies that are logically implied by F .
 - If $A \rightarrow B$ and $B \rightarrow C$, then we can infer that $A \rightarrow C$
- The set of **all** functional dependencies logically implied by F is the **closure** of F .
- We denote the *closure* of F by \mathbf{F}^+ .

Closure of a Set of Functional Dependencies

- We can compute F^+ , the closure of F , by repeatedly applying **Armstrong's Axioms**:
 - **Reflexive rule:** if $\beta \subseteq \alpha$, then $\alpha \rightarrow \beta$
 - **Augmentation rule:** if $\alpha \rightarrow \beta$, then $\gamma \alpha \rightarrow \gamma \beta$
 - **Transitivity rule:** if $\alpha \rightarrow \beta$, and $\beta \rightarrow \gamma$, then $\alpha \rightarrow \gamma$
- These rules are
 - **Sound** -- generate only functional dependencies that actually hold, and
 - **Complete** -- generate all functional dependencies that hold.

Closure of Functional Dependencies (Cont.)

- Additional rules:
 - **Union rule:** If $\alpha \rightarrow \beta$ holds and $\alpha \rightarrow \gamma$ holds, then $\alpha \rightarrow \beta \gamma$ holds.
 - **Decomposition rule:** If $\alpha \rightarrow \beta \gamma$ holds, then $\alpha \rightarrow \beta$ holds and $\alpha \rightarrow \gamma$ holds.
 - **Pseudotransitivity rule:** If $\alpha \rightarrow \beta$ holds and $\beta \rightarrow \delta$ holds, then $\alpha \gamma \rightarrow \delta$ holds.
- The above rules can be inferred from Armstrong's axioms.

Procedure for Computing F^+

- To compute the closure of a set of functional dependencies F :

$$F^+ = F$$

repeat

for each functional dependency f in F^+

 apply reflexivity and augmentation rules on f

 add the resulting functional dependencies to F^+

for each pair of functional dependencies f_1 and f_2 in F^+

if f_1 and f_2 can be combined using transitivity

then add the resulting functional dependency to

$$F^+$$

until F^+ does not change any further

- **NOTE:** We shall see an alternative procedure for this task later

Closure of Attribute Sets

- Given a set of attributes α , define the ***closure*** of α **under F** (denoted by α^+) as the set of attributes that are functionally determined by α under F
- Algorithm to compute α^+ , the closure of α under F

```
result :=  $\alpha$ ;  
while (changes to result) do  
  for each  $\beta \rightarrow \gamma$  in  $F$  do  
    begin  
      if  $\beta \subseteq \text{result}$  then result := result  $\cup$   $\gamma$   
    end
```

Uses of Attribute Closure

There are several uses of the attribute closure algorithm:

- Testing for superkey:
 - To test if α is a superkey, we compute α^+ , and check if α^+ contains all attributes of R .
- Testing functional dependencies
 - To check if a functional dependency $\alpha \rightarrow \beta$ holds (or, in other words, is in F^+), just check if $\beta \subseteq \alpha^+$.
 - That is, we compute α^+ by using attribute closure, and then check if it contains β .
 - Is a simple and cheap test, and very useful
- Computing closure of F
 - For each $\gamma \subseteq R$, we find the closure γ^+ , and for each $S \subseteq \gamma^+$, we output a functional dependency $\gamma \rightarrow S$.

Canonical Cover

- Suppose that we have a set of functional dependencies F on a relation schema. Whenever a user performs an update on the relation, the database system must ensure that the update does not violate any functional dependencies; that is, all the functional dependencies in F are satisfied in the new database state.
- If an update violates any functional dependencies in the set F , the system must roll back the update.
- We can reduce the effort spent in checking for violations by testing a simplified set of functional dependencies that has the same closure as the given set.
- This simplified set is termed the **canonical cover**
- To define canonical cover we must first define **extraneous attributes**.
 - An attribute of a functional dependency in F is **extraneous** if we can remove it without changing F^+

Extraneous Attributes

- Removing an attribute from the left side of a functional dependency could make it a stronger constraint.
 - For example, if we have $AB \rightarrow C$ and remove B, we get the possibly stronger result $A \rightarrow C$. It may be stronger because $A \rightarrow C$ logically implies $AB \rightarrow C$, but $AB \rightarrow C$ does not, on its own, logically imply $A \rightarrow C$
- But, depending on what our set F of functional dependencies happens to be, we may be able to remove B from $AB \rightarrow C$ safely.
 - For example, suppose that
 - $F = \{AB \rightarrow C, A \rightarrow D, D \rightarrow C\}$
 - Then we can show that F logically implies $A \rightarrow C$, making extraneous in $AB \rightarrow C$.

Extraneous Attributes (Cont.)

- Removing an attribute from the right side of a functional dependency could make it a weaker constraint.
 - For example, if we have $AB \rightarrow CD$ and remove C, we get the possibly weaker result $AB \rightarrow D$. It may be weaker because using just $AB \rightarrow D$, we can no longer infer $AB \rightarrow C$.
- But, depending on what our set F of functional dependencies happens to be, we may be able to remove C from $AB \rightarrow CD$ safely.
 - For example, suppose that
$$F = \{ AB \rightarrow CD, A \rightarrow C \}.$$
 - Then we can show that even after replacing $AB \rightarrow CD$ by $AB \rightarrow D$, we can still infer $AB \rightarrow C$ and thus $AB \rightarrow CD$.

Extraneous Attributes

- An attribute of a functional dependency in F is **extraneous** if we can remove it without changing F^+
- Consider a set F of functional dependencies and the functional dependency $\alpha \rightarrow \beta$ in F .
 - **Remove from the left side:** Attribute A is **extraneous** in α if
 - $A \in \alpha$ and
 - F logically implies $(F - \{\alpha \rightarrow \beta\}) \cup \{(\alpha - A) \rightarrow \beta\}$.
 - **Remove from the right side:** Attribute A is **extraneous** in β if
 - $A \in \beta$ and
 - The set of functional dependencies
$$(F - \{\alpha \rightarrow \beta\}) \cup \{\alpha \rightarrow (\beta - A)\}$$
 logically implies F .
- *Note:* implication in the opposite direction is trivial in each of the cases above, since a “stronger” functional dependency always implies a weaker one

Testing if an Attribute is Extraneous

- Let R be a relation schema and let F be a set of functional dependencies that hold on R . Consider an attribute in the functional dependency $\alpha \rightarrow \beta$.
- To test if attribute $A \in \beta$ is extraneous in β
 - Consider the set:
$$F' = (F - \{\alpha \rightarrow \beta\}) \cup \{\alpha \rightarrow (\beta - A)\},$$
 - check that α^+ contains A ; if it does, A is extraneous in β
- To test if attribute $A \in \alpha$ is extraneous in α
 - Let $\gamma = \alpha - \{A\}$. Check if $\gamma \rightarrow \beta$ can be inferred from F .
 - Compute γ^+ using the dependencies in F
 - If γ^+ includes all attributes in β then , A is extraneous in α

Examples of Extraneous Attributes

- Let $F = \{AB \rightarrow CD, A \rightarrow E, E \rightarrow C\}$
- To check if C is extraneous in $AB \rightarrow CD$, we:
 - Compute the attribute closure of AB under $F = \{AB \rightarrow D, A \rightarrow E, E \rightarrow C\}$
 - The closure is $ABCDE$, which includes CD
 - This implies that C is extraneous

Canonical Cover

A **canonical cover** for F is a set of dependencies F_c such that

- F logically implies all dependencies in F_c , and
- F_c logically implies all dependencies in F , and
- No functional dependency in F_c contains an extraneous attribute, and
- Each left side of functional dependency in F_c is unique. That is, there are no two dependencies in F_c
 - $\alpha_1 \rightarrow \beta_1$ and $\alpha_2 \rightarrow \beta_2$ such that
 - $\alpha_1 = \alpha_2$

Canonical Cover

- To compute a canonical cover for F :

repeat

 Use the union rule to replace any dependencies in F of the form

$$\alpha_1 \rightarrow \beta_1 \text{ and } \alpha_1 \rightarrow \beta_2 \text{ with } \alpha_1 \rightarrow \beta_1 \beta_2$$

 Find a functional dependency $\alpha \rightarrow \beta$ in F_c with an extraneous attribute either in α or in β

 /* Note: test for extraneous attributes done using F_c , not F^* */

 If an extraneous attribute is found, delete it from $\alpha \rightarrow \beta$

until (F_c not change)

- Note: Union rule may become applicable after some extraneous attributes have been deleted, so it has to be re-applied

Example: Computing a Canonical Cover

- $R = (A, B, C)$
 $F = \{A \rightarrow BC$
 $B \rightarrow C$
 $A \rightarrow B$
 $AB \rightarrow C\}$
- Combine $A \rightarrow BC$ and $A \rightarrow B$ into $A \rightarrow BC$
 - Set is now $\{A \rightarrow BC, B \rightarrow C, AB \rightarrow C\}$
- A is extraneous in $AB \rightarrow C$
 - Check if the result of deleting A from $AB \rightarrow C$ is implied by the other dependencies
 - Yes: in fact, $B \rightarrow C$ is already present!
 - Set is now $\{A \rightarrow BC, B \rightarrow C\}$
- C is extraneous in $A \rightarrow BC$
 - Check if $A \rightarrow C$ is logically implied by $A \rightarrow B$ and the other dependencies
 - Yes: using transitivity on $A \rightarrow B$ and $B \rightarrow C$.
 - Can use attribute closure of A in more complex cases
- The canonical cover is:
 - $A \rightarrow B$
 - $B \rightarrow C$

Dependency Preservation

- Let F_i be the set of dependencies F^+ that include only attributes in R_i .
 - A decomposition is **dependency preserving**, if
$$(F_1 \cup F_2 \cup \dots \cup F_n)^+ = F^+$$
- Using the above definition, testing for dependency preservation take exponential time.
- Note that if a decomposition is NOT dependency preserving then checking updates for violation of functional dependencies may require computing joins, which is expensive.

Dependency Preservation (Cont.)

- Let F be the set of dependencies on schema R and let R_1, R_2, \dots, R_n be a decomposition of R .
- The restriction of F to R_i is the set F_i of all functional dependencies in F^+ that include **only** attributes of R_i .
- Since all functional dependencies in a restriction involve attributes of only one relation schema, it is possible to test such a dependency for satisfaction by checking only one relation.
- Note that the definition of restriction uses all dependencies in F^+ , not just those in F .
- The set of restrictions F_1, F_2, \dots, F_n is the set of functional dependencies that can be checked efficiently.

Testing for Dependency Preservation

- To check if a dependency $\alpha \rightarrow \beta$ is preserved in a decomposition of R into R_1, R_2, \dots, R_n , we apply the following test (with attribute closure done with respect to F)
 - $result = \alpha$
 - repeat**
 - for each** R_i in the decomposition
 - $t = (result \cap R_i)^+ \cap R_i$
 - $result = result \cup t$
 - until** ($result$ does not change)
 - If $result$ contains all attributes in β , then the functional dependency $\alpha \rightarrow \beta$ is preserved.
- We apply the test on all dependencies in F to check if a decomposition is dependency preserving
- This procedure takes polynomial time, instead of the exponential time required to compute F^+ and $(F_1 \cup F_2 \cup \dots \cup F_n)^+$

Example

- $R = (A, B, C)$
 $F = \{A \rightarrow B$
 $B \rightarrow C\}$
Key = {A}
- R is not in BCNF
- Decomposition $R_1 = (A, B)$, $R_2 = (B, C)$
 - R_1 and R_2 in BCNF
 - Lossless-join decomposition
 - Dependency preserving

Algorithm for Decomposition Using Functional Dependencies

Testing for BCNF

- To check if a non-trivial dependency $\alpha \rightarrow \beta$ causes a violation of BCNF
 1. compute α^+ (the attribute closure of α), and
 2. verify that it includes all attributes of R , that is, it is a superkey of R .
- **Simplified test:** To check if a relation schema R is in BCNF, it suffices to check only the dependencies in the given set F for violation of BCNF, rather than checking all dependencies in F^+ .
 - If none of the dependencies in F causes a violation of BCNF, then none of the dependencies in F^+ will cause a violation of BCNF either.
- However, **simplified test** using only F is incorrect when testing a relation in a decomposition of R
 - Consider $R = (A, B, C, D, E)$, with $F = \{ A \rightarrow B, BC \rightarrow D \}$
 - Decompose R into $R_1 = (A, B)$ and $R_2 = (A, C, D, E)$
 - Neither of the dependencies in F contain only attributes from (A, C, D, E) so we might be misled into thinking R_2 satisfies BCNF.
 - In fact, dependency $AC \rightarrow D$ in F^+ shows R_2 is not in BCNF.

Testing Decomposition for BCNF

To check if a relation R_i in a decomposition of R is in BCNF

- Either test R_i for BCNF with respect to the **restriction** of F^+ to R_i (that is, all FDs in F^+ that contain only attributes from R_i)
- Or use the original set of dependencies F that hold on R , but with the following test:
 - for every set of attributes $\alpha \subseteq R_i$, check that α^+ (the attribute closure of α) either includes no attribute of $R_i - \alpha$, or includes all attributes of R_i .
 - If the condition is violated by some $\alpha \rightarrow \beta$ in F^+ , the dependency
$$\alpha \rightarrow (\alpha^+ - \alpha) \cap R_i$$
can be shown to hold on R_i , and R_i violates BCNF.
 - We use above dependency to decompose R_i

BCNF Decomposition Algorithm

```
result := {R};  
done := false;  
compute  $F^+$ ;  
while (not done) do  
  if (there is a schema  $R_i$  in result that is not in BCNF)  
    then begin  
      let  $\alpha \rightarrow \beta$  be a nontrivial functional dependency that  
      holds on  $R_i$  such that  $\alpha \rightarrow R_i$  is not in  $F^+$ ,  
      and  $\alpha \cap \beta = \emptyset$ ;  
      result := (result -  $R_i$ )  $\cup$  ( $R_i - \beta$ )  $\cup$  ( $\alpha, \beta$ );  
    end  
  else done := true;
```

Note: each R_i is in BCNF, and decomposition is lossless-join.

Example of BCNF Decomposition

- $\text{class}(\text{course_id}, \text{title}, \text{dept_name}, \text{credits}, \text{sec_id}, \text{semester}, \text{year}, \text{building}, \text{room_number}, \text{capacity}, \text{time_slot_id})$
- Functional dependencies:
 - $\text{course_id} \rightarrow \text{title}, \text{dept_name}, \text{credits}$
 - $\text{building}, \text{room_number} \rightarrow \text{capacity}$
 - $\text{course_id}, \text{sec_id}, \text{semester}, \text{year} \rightarrow \text{building}, \text{room_number}, \text{time_slot_id}$
- A candidate key $\{\text{course_id}, \text{sec_id}, \text{semester}, \text{year}\}$.
- BCNF Decomposition:
 - $\text{course_id} \rightarrow \text{title}, \text{dept_name}, \text{credits}$ holds
 - but course_id is not a superkey.
 - We replace class by:
 - $\text{course}(\text{course_id}, \text{title}, \text{dept_name}, \text{credits})$
 - $\text{class-1}(\text{course_id}, \text{sec_id}, \text{semester}, \text{year}, \text{building}, \text{room_number}, \text{capacity}, \text{time_slot_id})$

BCNF Decomposition (Cont.)

- *course* is in BCNF
 - How do we know this?
- *building, room_number*→*capacity* holds on *class-1*
 - but $\{building, room_number\}$ is not a superkey for *class-1*.
 - We replace *class-1* by:
 - *classroom* (*building, room_number, capacity*)
 - *section* (*course_id, sec_id, semester, year, building, room_number, time_slot_id*)
- *classroom* and *section* are in BCNF.

Third Normal Form

- There are some situations where
 - BCNF is not dependency preserving, and
 - efficient checking for FD violation on updates is important
- Solution: define a weaker normal form, called Third Normal Form (3NF)
 - Allows some redundancy (with resultant problems; we will see examples later)
 - But functional dependencies can be checked on individual relations without computing a join.
 - There is always a lossless-join, dependency-preserving decomposition into 3NF.

3NF Example -- Relation *dept_advisor*

- $\text{dept_advisor}(s_ID, i_ID, \text{dept_name})$
 $F = \{s_ID, \text{dept_name} \rightarrow i_ID, i_ID \rightarrow \text{dept_name}\}$
- Two candidate keys: $s_ID, \text{dept_name}$, and i_ID, s_ID
- R is in 3NF
 - $s_ID, \text{dept_name} \rightarrow i_ID \quad s_ID$
 - dept_name is a superkey
 - $i_ID \rightarrow \text{dept_name}$
 - dept_name is contained in a candidate key

Testing for 3NF

- Need to check only FDs in F , need not check all FDs in F^+ .
- Use attribute closure to check for each dependency $\alpha \rightarrow \beta$, if α is a superkey.
- If α is not a superkey, we have to verify if each attribute in β is contained in a candidate key of R
 - This test is rather more expensive, since it involve finding candidate keys
 - Testing for 3NF has been shown to be NP-hard
 - Interestingly, decomposition into third normal form (described shortly) can be done in polynomial time

3NF Decomposition Algorithm

Let F_c be a canonical cover for F ;

$i := 0$;

for each functional dependency $\alpha \rightarrow \beta$ in F_c **do**

if none of the schemas R_j , $1 \leq j \leq i$ contains $\alpha \beta$

then begin

$i := i + 1$;

$R_i := \alpha \beta$

end

if none of the schemas R_j , $1 \leq j \leq i$ contains a candidate key for R

then begin

$i := i + 1$;

$R_i :=$ any candidate key for R ;

end

/* Optionally, remove redundant relations */

repeat

if any schema R_j is contained in another schema R_k

then /* delete R_j */

$R_j = R;;$

$i = i - 1$;

return (R_1, R_2, \dots, R_i)

3NF Decomposition Algorithm (Cont.)

Above algorithm ensures

- Each relation schema R_i is in 3NF
- Decomposition is dependency preserving and lossless-join
- Proof of correctness is at end of this presentation (click here)

3NF Decomposition: An Example

- Relation schema:
 $\text{cust_banker_branch} = (\underline{\text{customer_id}}, \underline{\text{employee_id}}, \text{branch_name}, \text{type})$
- The functional dependencies for this relation schema are:
 - $\text{customer_id}, \text{employee_id} \rightarrow \text{branch_name}, \text{type}$
 - $\text{employee_id} \rightarrow \text{branch_name}$
 - $\text{customer_id}, \text{branch_name} \rightarrow \text{employee_id}$
- We first compute a canonical cover
 - branch_name is extraneous in the r.h.s. of the 1st dependency
 - No other attribute is extraneous, so we get $F_C =$
 $\text{customer_id}, \text{employee_id} \rightarrow \text{type}$
 $\text{employee_id} \rightarrow \text{branch_name}$
 $\text{customer_id}, \text{branch_name} \rightarrow \text{employee_id}$

3NF Decomposition Example (Cont.)

- The **for** loop generates following 3NF schema:
 - (*customer_id, employee_id, type*)
 - (*employee_id, branch_name*)
 - (*customer_id, branch_name, employee_id*)
- Observe that (*customer_id, employee_id, type*) contains a candidate key of the original schema, so no further relation schema needs be added
- At end of for loop, detect and delete schemas, such as (*employee_id, branch_name*), which are subsets of other schemas
 - result will not depend on the order in which FDs are considered
- The resultant simplified 3NF schema is:
 - (*customer_id, employee_id, type*)
 - (*customer_id, branch_name, employee_id*)

Comparison of BCNF and 3NF

- It is always possible to decompose a relation into a set of relations that are in 3NF such that:
 - The decomposition is lossless
 - The dependencies are preserved
- It is always possible to decompose a relation into a set of relations that are in BCNF such that:
 - The decomposition is lossless
 - It may not be possible to preserve dependencies.

Design Goals

- Goal for a relational database design is:
 - BCNF.
 - Lossless join.
 - Dependency preservation.
- If we cannot achieve this, we accept one of
 - Lack of dependency preservation
 - Redundancy due to use of 3NF
- Interestingly, SQL does not provide a direct way of specifying functional dependencies other than superkeys.

Can specify FDs using assertions, but they are expensive to test,
(and currently not supported by any of the widely used databases!)
- Even if we had a dependency preserving decomposition, using SQL
we would not be able to efficiently test a functional dependency
whose left hand side is not a key.

Multivalued Dependencies

Multivalued Dependencies (MVDs)

- Suppose we record names of children, and phone numbers for instructors:
 - $inst_child(ID, child_name)$
 - $inst_phone(ID, phone_number)$
- If we were to combine these schemas to get
 - $inst_info(ID, child_name, phone_number)$
 - Example data:
 - (99999, David, 512-555-1234)
 - (99999, David, 512-555-4321)
 - (99999, William, 512-555-1234)
 - (99999, William, 512-555-4321)
- This relation is in BCNF
 - Why?

Multivalued Dependencies

- Let R be a relation schema and let $\alpha \subseteq R$ and $\beta \subseteq R$. The **multivalued dependency**

$$\alpha \rightarrow\!\!\!\rightarrow \beta$$

holds on R if in any legal relation $r(R)$, for all pairs of tuples t_1 and t_2 in r such that $t_1[\alpha] = t_2[\alpha]$, there exist tuples t_3 and t_4 in r such that:

$$\begin{aligned}t_1[\alpha] &= t_2[\alpha] = t_3[\alpha] = t_4[\alpha] \\t_3[\beta] &= t_1[\beta] \\t_3[R - \beta] &= t_2[R - \beta] \\t_4[\beta] &= t_2[\beta] \\t_4[R - \beta] &= t_1[R - \beta]\end{aligned}$$

MVD -- Tabular representation

- Tabular representation of $\alpha \rightarrow\!\!\!\rightarrow \beta$

	α	β	$R - \alpha - \beta$
t_1	$a_1 \dots a_i$	$a_{i+1} \dots a_j$	$a_{j+1} \dots a_n$
t_2	$a_1 \dots a_i$	$b_{i+1} \dots b_j$	$b_{j+1} \dots b_n$
t_3	$a_1 \dots a_i$	$a_{i+1} \dots a_j$	$b_{j+1} \dots b_n$
t_4	$a_1 \dots a_i$	$b_{i+1} \dots b_j$	$a_{j+1} \dots a_n$

MVD (Cont.)

- Let R be a relation schema with a set of attributes that are partitioned into 3 nonempty subsets.

Y, Z, W

- We say that $Y \rightarrow\!\!\!\rightarrow Z$ (Y **multidetermines** Z) if and only if for all possible relations $r(R)$

$\langle y_1, z_1, w_1 \rangle \in r$ and $\langle y_1, z_2, w_2 \rangle \in r$

then

$\langle y_1, z_1, w_2 \rangle \in r$ and $\langle y_1, z_2, w_1 \rangle \in r$

- Note that since the behavior of Z and W are identical it follows that $Y \rightarrow\!\!\!\rightarrow Z$ if $Y \rightarrow\!\!\!\rightarrow W$

Example

- In our example:

$ID \rightarrow\rightarrow child_name$

$ID \rightarrow\rightarrow phone_number$

- The above formal definition is supposed to formalize the notion that given a particular value of Y (ID) it has associated with it a set of values of Z ($child_name$) and a set of values of W ($phone_number$), and these two sets are in some sense independent of each other.
- Note:
 - If $Y \rightarrow Z$ then $Y \rightarrow\rightarrow Z$
 - Indeed we have (in above notation) $Z_1 = Z_2$
The claim follows.

Use of Multivalued Dependencies

- We use multivalued dependencies in two ways:
 1. To test relations to **determine** whether they are legal under a given set of functional and multivalued dependencies
 2. To specify **constraints** on the set of legal relations. We shall concern ourselves *only* with relations that satisfy a given set of functional and multivalued dependencies.
- If a relation r fails to satisfy a given multivalued dependency, we can construct a relations r' that does satisfy the multivalued dependency by adding tuples to r .

Theory of MVDs

- From the definition of multivalued dependency, we can derive the following rule:
 - If $\alpha \rightarrow \beta$, then $\alpha \rightarrow\rightarrow \beta$
- That is, every functional dependency is also a multivalued dependency
- The **closure** D^+ of D is the set of all functional and multivalued dependencies logically implied by D .
 - We can compute D^+ from D , using the formal definitions of functional dependencies and multivalued dependencies.
 - We can manage with such reasoning for very simple multivalued dependencies, which seem to be most common in practice
 - For complex dependencies, it is better to reason about sets of dependencies using a system of inference rules (Appendix C).

Fourth Normal Form

- A relation schema R is in **4NF** with respect to a set D of functional and multivalued dependencies if for all multivalued dependencies in D^+ of the form $\alpha \rightarrow\rightarrow \beta$, where $\alpha \subseteq R$ and $\beta \subseteq R$, at least one of the following hold:
 - $\alpha \rightarrow\rightarrow \beta$ is trivial (i.e., $\beta \subseteq \alpha$ or $\alpha \cup \beta = R$)
 - α is a superkey for schema R
- If a relation is in 4NF it is in BCNF

Restriction of Multivalued Dependencies

- The restriction of D to R_i is the set D_i consisting of
 - All functional dependencies in D^+ that include only attributes of R_i
 - All multivalued dependencies of the form
$$\alpha \rightarrow\rightarrow (\beta \cap R_i)$$
where $\alpha \subseteq R_i$ and $\alpha \rightarrow\rightarrow \beta$ is in D^+

4NF Decomposition Algorithm

result: = { R };

done := false;

compute D^+ ;

Let D_i denote the restriction of D^+ to R_i

while (**not** *done*)

if (there is a schema R_i in *result* that is not in 4NF) **then**

begin

let $\alpha \rightarrow\!\!\rightarrow \beta$ be a nontrivial multivalued dependency that holds
on R_i such that $\alpha \rightarrow R_i$ is not in D_i , and $\alpha \cap \beta = \emptyset$;

result := (*result* - R_i) \cup (R_i - β) \cup (α, β);

end

else *done*:= true;

Note: each R_i is in 4NF, and decomposition is lossless-join

Example

- $R = (A, B, C, G, H, I)$
 $F = \{ A \rightarrow\!\!\!\rightarrow B$
 $B \rightarrow\!\!\!\rightarrow HI$
 $CG \rightarrow\!\!\!\rightarrow H \}$
- R is not in 4NF since $A \rightarrow\!\!\!\rightarrow B$ and A is not a superkey for R
- Decomposition
 - a) $R_1 = (A, B)$ $(R_1$ is in 4NF)
 - b) $R_2 = (A, C, G, H, I)$ $(R_2$ is not in 4NF, decompose into R_3 and R_4)
 - c) $R_3 = (C, G, H)$ $(R_3$ is in 4NF)
 - d) $R_4 = (A, C, G, I)$ $(R_4$ is not in 4NF, decompose into R_5 and R_6)
 - $A \rightarrow\!\!\!\rightarrow B$ and $B \rightarrow\!\!\!\rightarrow HI \Rightarrow A \rightarrow\!\!\!\rightarrow HI$, (MVD transitivity), and
 - and hence $A \rightarrow\!\!\!\rightarrow I$ (*MVD restriction to R_4*)
 - e) $R_5 = (A, I)$ $(R_5$ is in 4NF)
 - f) $R_6 = (A, C, G)$ $(R_6$ is in 4NF)

Additional issues

Further Normal Forms

- **Join dependencies** generalize multivalued dependencies
 - lead to **project-join normal form (PJNF)** (also called **fifth normal form**)
- A class of even more general constraints, leads to a normal form called **domain-key normal form**.
- Problem with these generalized constraints: are hard to reason with, and no set of sound and complete set of inference rules exists.
- Hence rarely used

Overall Database Design Process

We have assumed schema R is given

- R could have been generated when converting E-R diagram to a set of tables.
- R could have been a single relation containing *all* attributes that are of interest (called **universal relation**).
- Normalization breaks R into smaller relations.
- R could have been the result of some ad hoc design of relations, which we then test/convert to normal form.

ER Model and Normalization

- When an E-R diagram is carefully designed, identifying all entities correctly, the tables generated from the E-R diagram should not need further normalization.
- However, in a real (imperfect) design, there can be functional dependencies from non-key attributes of an entity to other attributes of the entity
 - Example: an *employee* entity with
 - attributes
department_name and *building*,
 - functional dependency
 $department_name \rightarrow building$
 - Good design would have made department an entity
- Functional dependencies from non-key attributes of a relationship set possible, but rare --- most relationships are binary

Denormalization for Performance

- May want to use non-normalized schema for performance
- For example, displaying *prereqs* along with *course_id*, and *title* requires join of *course* with *prereq*
- Alternative 1: Use denormalized relation containing attributes of *course* as well as *prereq* with all above attributes
 - faster lookup
 - extra space and extra execution time for updates
 - extra coding work for programmer and possibility of error in extra code
- Alternative 2: use a materialized view defined a *course prereq*
 - Benefits and drawbacks same as above, except no extra coding work for programmer and avoids possible errors \bowtie

Other Design Issues

- Some aspects of database design are not caught by normalization
- Examples of bad database design, to be avoided:
Instead of *earnings* (*company_id*, *year*, *amount*), use
 - *earnings_2004*, *earnings_2005*, *earnings_2006*, etc., all on the schema (*company_id*, *earnings*).
 - Above are in BCNF, but make querying across years difficult and needs new table each year
 - *company_year* (*company_id*, *earnings_2004*, *earnings_2005*, *earnings_2006*)
 - Also in BCNF, but also makes querying across years difficult and requires new attribute each year.
 - Is an example of a **crosstab**, where values for one attribute become column names
 - Used in spreadsheets, and in data analysis tools

Modeling Temporal Data

- **Temporal data** have an association time interval during which the data are *valid*.
- A **snapshot** is the value of the data at a particular point in time
- Several proposals to extend ER model by adding valid time to
 - attributes, e.g., address of an instructor at different points in time
 - entities, e.g., time duration when a student entity exists
 - relationships, e.g., time during which an instructor was associated with a student as an advisor.
- But no accepted standard
- Adding a temporal component results in functional dependencies like
$$ID \rightarrow street, city$$
not holding, because the address varies over time
- A **temporal functional dependency** $X \rightarrow Y$ holds on schema R if the functional dependency $X \rightarrow Y$ holds on all snapshots for all legal instances $r(R)$.

Modeling Temporal Data (Cont.)

- In practice, database designers may add start and end time attributes to relations
 - E.g., $\text{course}(\text{course_id}, \text{course_title})$ is replaced by $\text{course}(\text{course_id}, \text{course_title}, \text{start}, \text{end})$
 - Constraint: no two tuples can have overlapping valid times
 - Hard to enforce efficiently
- Foreign key references may be to current version of data, or to data at a point in time
 - E.g., student transcript should refer to course information at the time the course was taken

End of Chapter 7

Proof of Correctness of 3NF Decomposition Algorithm

Correctness of 3NF Decomposition Algorithm

- 3NF decomposition algorithm is dependency preserving (since there is a relation for every FD in F_c)
- Decomposition is lossless
 - A candidate key (C) is in one of the relations R_i in decomposition
 - Closure of candidate key under F_c must contain all attributes in R .
 - Follow the steps of attribute closure algorithm to show there is only one tuple in the join result for each tuple in R_i

Correctness of 3NF Decomposition Algorithm (Cont.)

- Claim: if a relation R_i is in the decomposition generated by the above algorithm, then R_i satisfies 3NF.
- Proof:
 - Let R_i be generated from the dependency $\alpha \rightarrow \beta$
 - Let $\gamma \rightarrow B$ be any non-trivial functional dependency on R_i . (We need only consider FDs whose right-hand side is a single attribute.)
 - Now, B can be in either β or α but not in both. Consider each case separately.

Correctness of 3NF Decomposition (Cont.)

- Case 1: If B in β :
 - If γ is a superkey, the 2nd condition of 3NF is satisfied
 - Otherwise α must contain some attribute not in γ
 - Since $\gamma \rightarrow B$ is in F^+ it must be derivable from F_c , by using attribute closure on γ .
 - Attribute closure not have used $\alpha \rightarrow \beta$. If it had been used, α must be contained in the attribute closure of γ , which is not possible, since we assumed γ is not a superkey.
 - Now, using $\alpha \rightarrow (\beta - \{B\})$ and $\gamma \rightarrow B$, we can derive $\alpha \rightarrow B$ (since $\gamma \subseteq \alpha \beta$, and $B \notin \gamma$ since $\gamma \rightarrow B$ is non-trivial)
 - Then, B is extraneous in the right-hand side of $\alpha \rightarrow \beta$; which is not possible since $\alpha \rightarrow \beta$ is in F_c .
 - Thus, if B is in β then γ must be a superkey, and the second condition of 3NF must be satisfied.

Correctness of 3NF Decomposition (Cont.)

- Case 2: B is in α .
 - Since α is a candidate key, the third alternative in the definition of 3NF is trivially satisfied.
 - In fact, we cannot show that γ is a superkey.
 - This shows exactly why the third alternative is present in the definition of 3NF.

Q.E.D.

Example: Constraints on Entity Set

- Consider relation obtained from Hourly_Emps:
 - Hourly_Emps (ssn, name, lot, rating, hrly_wages, hrs_worked)
- Notation: We will denote this relation schema by listing the attributes: SNLRWH
 - This is really the set of attributes {S,N,L,R,W,H}.
 - Sometimes, we will refer to all attributes of a relation by using the relation name. (e.g., Hourly_Emps for SNLRWH)
- Some FDs on Hourly_Emps:
 - ssn is the key: $S \rightarrow SNLRWH$
 - rating determines hrly_wages: $R \rightarrow W$

Example (Contd.)

R	W
8	10
5	7

Hourly_Emps2

S	N	L	R	H
123-22-3666	Attishoo	48	8	40
231-31-5368	Smiley	22	8	30
131-24-3650	Smethurst	35	5	30
434-26-3751	Guldu	35	5	32
612-67-4134	Madayan	35	8	40

S	N	L	R	W	H
123-22-3666	Attishoo	48	8	10	40
231-31-5368	Smiley	22	8	10	30
131-24-3650	Smethurst	35	5	7	30
434-26-3751	Guldu	35	5	7	32
612-67-4134	Madayan	35	8	10	40

Solution

Decompose the relation:

- Hourly_Emps (ssn, name, lot, rating, hrly_wages, hrs_worked)
 - Into set of relations:
 - Hourly_Emps(ssn, name, lot, rating, hours_worked)
 - Rating_Wages(rating, hrly_wages)
-
- What happened to update anomalies?
 - We need to find out the basis for decomposing a relation to get rid of update anomalies

Functional Dependency

- FD is a many-to-one relationship from one set attributes to another
- Example: there is a FD from the set of attributes {S#,P#} to the set of attributes {QTY}
- For any given value for pair of attributes S# and P#, there is just one corresponding value of attribute QTY, but, many distinct values of the pair of attributes S# and P# can have the same corresponding value for attribute QTY

Functional Dependencies

- Constraints on the set of legal relations
- Require that the value for a certain set of attributes determines uniquely the value for another set of attributes
- A functional dependency is a generalization of the notion of a *key*

Reasoning About FDs

- Given some FDs, we can usually infer additional FDs:
 - $ssn \rightarrow did$, $did \rightarrow lot$ implies $ssn \rightarrow lot \rightarrow$
- An FD f is implied by a set of FDs F if f holds whenever all FDs in F hold.
 - *closure of F* is the set of all FDs that are implied by F
 - It is constraint in the real world and hence be obeyed
 - Declare FD and make sure that it is followed (integrity constraint)
